

Title: Investigating the mechanistic and temporal regulation of inhibitory synapse elimination during cerebral ischemia.

Abstract: Inhibitory synapses are crucial for maintaining correct neuronal excitability, which is important for efficient circuitry and proper brain function. Inhibitory GABA_A receptors (GABA_ARs) mediate the majority of fast synaptic inhibition in the brain. Thus, the number of postsynaptic GABA_ARs influences inhibitory strength. Shifts in neuronal excitability have been implicated in a variety of neurological disorders, including ischemia. The oxygen and glucose deprivation (OGD) observed during ischemic insult in hippocampal regions leads to synaptic depression through GABA_AR and gephyrin loss from synaptic sites. However, mechanisms that regulate GABA_AR declustering and gephyrin elimination following an ischemic insult remain undefined. In this project, I propose that GABA_AR declustering is mediated by calcineurin activity and this is the first step in facilitating synapse elimination. Furthermore, I speculate a role of the cysteine protease, Calpain, in mediating gephyrin loss during OGD. Based on this, I plan to investigate (i) mechanisms of synaptic GABA_AR declustering and gephyrin elimination in hippocampal pyramidal neurons following OGD (ii) probe the temporal regulation to determine the sequential flow of events promoting GABA_AR and gephyrin loss and (iii) use an in vivo model of cerebral ischemia to compare cell-type specific mechanisms in the CA1 hippocampus.
